The Q-network in DQN

state / action	a_0	a_1	a_2	a_3
\mathbf{s}_0	0.66	0.88*	0.81	0.73
\mathbf{s}_1	0.73	0.63	0.9*	0.43
\mathbf{s}_2	0.73	0.9	0.95*	0.73
\mathbf{s}_3	0.81	0.9	1.0*	0.81
\mathbf{s}_4	0.81	1.0*	0.81	0.9
s_5	0.9	1.0*	0.0	0.9

DQN

- lacktriangle Parametrized representation of the critic $\hat{Q}_{m{\phi}}^{\pi_{m{ heta}}}(\mathbf{s}_t,\mathbf{a}_t)$
- Q-network equivalent to the Q-Table (with an infinity of state rows)
- ▶ For each observed $(\mathbf{s}_t, \mathbf{a}_t, r_t, \mathbf{s}_{t+1})$:

$$Q(\mathbf{s}_t, \mathbf{a}_t) \leftarrow Q(\mathbf{s}_t, \mathbf{a}_t) + \alpha[r_t + \gamma \max_{\mathbf{a} \in A} Q(\mathbf{s}_{t+1}, \mathbf{a}) - Q(\mathbf{s}_t, \mathbf{a}_t)]$$

- ► Select action by finding $\max_{\mathbf{a} \in A} Q(\mathbf{s}, \mathbf{a})$ (as in Q-LEARNING)
- Limitation: requires one output neuron per action

Moving to continuous actions

- Two things become too hard:
 - ► Selecting actions by finding $\max_{\mathbf{a} \in A} Q(\mathbf{s}, \mathbf{a})$
 - ► Computing $\max_{\mathbf{a} \in A} Q(\mathbf{s}_{t+1}, \mathbf{a})$ in the update rule

- Three classes of solutions
 - 1. Use an easily optimized model (e.g. convex) (NAF, Wang et al. 2016)
 - 2. Sample a limited set of actions (QT-Opt, Kalashnikov et al., 2018)
 - 3. DDPG: train a side estimator of the best action (also true of SAC)

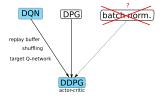

Dmitry Kalashnikov, Alex Irpan, Peter Pastor, Julian Ibarz, Alexander Herzog, Eric Jang, Deirdre Quillen, Ethan Holly, Mrinal Kalakrishnan, Vincent Vanhoucke, et al. Qt-Opt: Scalable deep reinforcement learning for vision-based robotic manipulation. arXiv preprint arXiv:1806.10293, 2018

DDPG: ancestors

- Most of the actor-critic theory for continuous problem is for stochastic policies (policy gradient theorem, compatible features, etc.)
- DPG: an efficient gradient computation for deterministic policies, with proof of convergence
- Batch norm: inconclusive studies about impact
- ▶ Used on 32 classic control benchmarks, sometimes from pixels

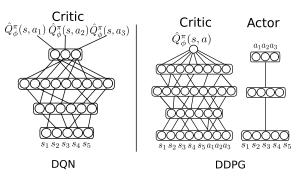

Silver, D., Lever, G., Heess, N., Degris, T., Wierstra, D., & Riedmiller, M. (2014) Deterministic policy gradient algorithms. In ICML

loffe, S. & Szegedy, C. (2015) Batch normalization: Accelerating deep network training by reducing internal covariate shift. arXiv preprint arXiv:1502.03167

General architecture

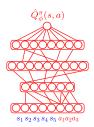

- Actor $\pi_{\theta}(\mathbf{a}_t|\mathbf{s}_t)$, critic $\hat{Q}_{\phi}^{\pi_{\theta}}(\mathbf{s}_t,\mathbf{a}_t)$ (a single output neuron)
- All updates based on SGD
- Adaptive gradient descent techniques tune the step size (RProp, RMSProp, Adagrad, Adam...)

Training the critic

Critic

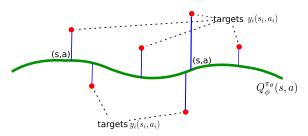

Same idea as in DQN, but for actor-critic rather than Q-LEARNING

- ▶ Supervised learning: minimize $L(\phi) = (y^*(\mathbf{s}, \mathbf{a}) \hat{F}_{\phi}(\mathbf{s}_i, \mathbf{a}_i | \phi))^2$
- For each sample i, the Q-network should minimize the RPE: $\delta_t = r_t + \gamma \hat{Q}^{\sigma\theta}_{\theta}(s_{t+1}, \pi(s_{t+1})) \hat{Q}^{\sigma\theta}_{\theta}(s_t, \mathbf{a}_t) \quad \text{it needs to tend to 0}$
- ► Given a minibatch of N samples $\{\mathbf{s}_i, \mathbf{a}_i, r_i, \mathbf{s}_{i+1}\}$ and a target network Q', compute $y_i = r_i + \gamma \hat{Q}' \frac{\sigma_{\theta'}}{\theta'}(\mathbf{s}_{i+1}, \pi(\mathbf{s}_{i+1}))$
- ightharpoonup And update ϕ by minimizing the loss function

$$L = 1/N \sum_{i} (y_i - \hat{Q}_{\phi}^{\pi \theta}(\mathbf{s}_i, \mathbf{a}_i | \phi))^2$$

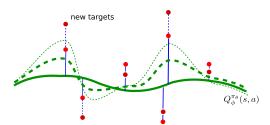

Learning the neural Q-function

- In the tabular case, each Q-value is updated separately
- In the continuous state and action setting, interdependencies between updates
- \triangleright Thus update ϕ by minimizing the squared TD loss function over minibatches

Trick 1: Stable Target Q-function

- ▶ The target $y_i = r_i + \gamma \max_a \hat{Q}^{\pi_{\theta}}_{\phi}(\mathbf{s}_{i+1}, a) | \phi)$ is itself a function of $\hat{Q}^{\pi_{\theta}}_{\phi}$
- ▶ Thus this is not truly supervised learning, and this is unstable
- Key idea: "periods of supervised learning"
- Compute the loss function from a separate target critic $\hat{Q}'_{\phi'}^{\pi_{\theta}}(...|\phi')$
- So rather compute $y_i = r_i + \gamma \max_a \hat{Q'}_{\phi'}^{\pi_{\theta}}(\mathbf{s}_{i+1}, a|\phi')$
- ▶ In DQN, $oldsymbol{\phi}'$ is updated to $oldsymbol{\phi}$ only each K iterations
- ▶ In DDPG, update ϕ' using $\phi' \leftarrow (1-\tau)\phi' + \tau\phi$ with a small gain τ

Training the actor We are in a certain state and the Actor is proposing a certain action We will evaluate this action with the critic. If we want to improve the actor, we pick a slightly different action and check if the Q value is higher or lower.

If it is higher we take it

We backpropagate the gradient of the a function, this is giving an error.

Then we train the actor with the error => actor improves

Critic $\hat{Q}^{\pi}(s,a)$ 0000 $s_1 \, s_2 \, s_3 \, s_4 \, s_5 \, a_1 a_2 a_3$

Actor

We also need an improved(trained) critic

Deterministic policy gradient theorem: the true policy gradient is

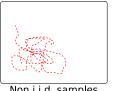

$$\nabla_{\boldsymbol{\theta}} \pi(\mathbf{s}_t, \mathbf{a}_t) = \mathbb{E}_{\mathbf{s}_t, \mathbf{a}_t \sim \pi_{\boldsymbol{\theta}}(.)} [\nabla_a \hat{Q}_{\boldsymbol{\phi}}^{\pi_{\boldsymbol{\theta}}}(\mathbf{s}_t, \mathbf{a}_t) \nabla_{\boldsymbol{\theta}} \pi(s|\boldsymbol{\theta})]$$
(1)

- $\nabla_a \hat{Q}_{\phi}^{\pi_{\theta}}(\mathbf{s}_t, \mathbf{a}_t)$ is used as error signal to update the actor weights.
- Comes from NFQCA
- $\nabla_a \hat{Q}_{\phi}^{\pi_{\theta}}(\mathbf{s}_t, \mathbf{a}_t)$ is a gradient over actions
- y = f(w.x + b) (symmetric roles of weights and inputs)
- Gradient over actions \sim gradient over weights

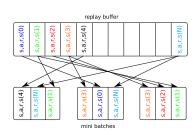

Trick2: Replay buffer shuffling

Non i.i.d. samples i.i.d. samples

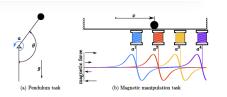

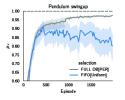

- Agent samples are not independent and identically distributed (i.i.d.)
- ▶ Shuffling a replay buffer (RB) makes them more i.i.d.
- ▶ It improves a lot the sample efficiency
- ▶ Recent data in the RB come from policies close to the current one

hyperparameter tau=1 => no target critic (network) => it was updated at each time stamp

Better idea to perturbate the weights. 18.22 video

Twin Delayed Deep Deterministic PG

- All descendants of Q-learning suffer from over-estimation bias
- ightharpoonup Clipping the critic from the knowledge of R_{max} helps
- ightharpoonup TD3: Introduce two critics $\hat{Q}_{m{\phi}_1}^{\pi_{m{\theta}}}$ and $\hat{Q}_{m{\phi}_2}^{\pi_{m{\theta}}}$
- Compute the TD-target as the minimum to reduce the over-estimation bias
- ► Less problem knowledge than critic clipping
- ► Next lesson: Soft Actor Critic
